Bisimulation

The architecture of **functional designs**

SA as studied at MFES (until now):

Interfaces: Components: Connectors: Configurations: Properties: Behavioural effects: Underlying maths: $\begin{array}{l} f :: \cdots \longrightarrow \cdots \\ f = \cdots \\ \vdots, \langle , \rangle, \times, +, \ldots \end{array}$

functions assembled by composition invariants (pre-, post-conditions) monads and Kleisli compostion universal algebra and relational calculus

Bisimulation

... can be extended to reactive systems?

Software Architecture is challenged by the continuous evolution towards very large, heterogeneous, highly dynamic computing systems, whose behaviour cannot be characterized in terms of a io-relation. In most cases, such a behaviour

- is potentially non-terminating,
- expresses a continued interaction with the system's environment and sub-systems which execute concurrently in distributed, often loosely coupled configurations.

Bisimulation

Behaviour & Interaction

[R. Milner, 1997]

Thus software, from being a prescription for how to do something — in Turing's terms a "list of instructions" — becomes much more akin to a description of behaviour, not only programmed on a computer, but occurring by hap or design inside or outside it.

[B. Jacobs, 2005]

The subject of Computer Science is not information processing or symbol manipulation, but generated behaviour.

Bisimulation

Behaviour & Interaction

[R. Milner, 1997]

Thus software, from being a prescription for how to do something — in Turing's terms a "list of instructions" — becomes much more akin to a description of behaviour, not only programmed on a computer, but occurring by hap or design inside or outside it.

[B. Jacobs, 2005]

The subject of Computer Science is not information processing or symbol manipulation, but generated behaviour.

Bisimulation

Reactive systems

Reactive system

system that computes by reacting to stimuli from its environment along its overall computation

- in contrast to sequential systems whose meaning is defined by the results of finite computations, the behaviour of reactive systems is mainly determined by interaction and mobility of non-terminating processes, evolving concurrently.
- observation ⇔ interaction
- behaviour ⇔ a structured record of interactions

automaton behaviour $\,\,\Leftrightarrow\,\,$ accepted language

Recall that finite automata recognize regular languages, i.e. generated by

•
$$L_1 + L_2 \triangleq L_1 \cup L_2$$
 (union)

•
$$L_1 \cdot L_2 \triangleq \{ st \mid s \in L_1, t \in L_2 \}$$
 (concatenation)

• $L^* \triangleq \{\epsilon\} \cup L \cup (L \cdot L) \cup (L \cdot L \cdot L) \cup ...$ (iteration)

Bisimulation

Automata

There is a syntax to specify such languages:

 $E ::= \epsilon \mid a \mid E + E \mid EE \mid E^*$

where $a \in \Sigma$.

- which regular expression specifies {*a*, *bc*}?
- and {*ca*, *cb*}?

and an algebra of regular expressions:

$$(E_1 + E_2) + E_3 = E_1 + (E_2 + E_3)$$

$$(E_1 + E_2) E_3 = E_1 E_3 + E_2 E_3$$

$$E_1 (E_2 E_1)^* = (E_1 E_2)^* E_1$$

Bisimulation

After thoughts

- ... need more general models and theories:
 - Several interaction points (\neq functions)
 - Non termination (no final states as in automata)
 - Need to distinguish normal from anomolous termination (eg deadlock)
 - Non determinisim should be taken seriously: the notion of equivalence based on accepted language is blind wrt non determinism

Labelled Transition Structure

Relational characterization A LTS over a set A of names is a pair

$$\langle U, \alpha \leftarrow : A \times U \leftarrow U \rangle$$

where

- $U = \{u_0, u_1, u_2, ...\}$ is a set of states
- $_{\alpha} \leftarrow : A \times U \leftarrow U$ is an arrow in Rel, capturing the transition relation,

often given as an A-indexed family of binary relations

$$u' \ _{lpha} \xleftarrow{a} u \ \Leftrightarrow \ \langle a, u' \rangle \ _{lpha} \longleftarrow u$$

or simply,

$$u' \xleftarrow{a} u \Leftrightarrow \langle a, u' \rangle_{\alpha} \longleftarrow u$$

Reachability

Definition

The reachability relation, $_{lpha} := A imes U \longleftarrow U$, is defined inductively

• $u \ _{\alpha} \xleftarrow{\epsilon} u$ for each $u \in U$, where $\epsilon \in A^*$ denotes the empty word;

• if
$$u'' \,_{\alpha} \xleftarrow{\sigma} u$$
 and $u' \,_{\alpha} \xleftarrow{a} u''$ then $u'' \,_{\alpha} \xleftarrow{\sigma a} u$, for $a \in A, \sigma \in A^*$

Reachable state

 $t \in U$ is reachable from $u \in U$ iff there is a word $\sigma \in A^*$ st $t \, _{\alpha} \stackrel{\sigma}{\longleftarrow} \, u$

Transposition

The power-transpose

Binary relations and powerset valued functions are equivalent: each other determines the other uniquely.

The existence and uniqueness of such a transformation leads to the identification of a transpose operator Λ characterized by the following universal property:

 $f = \Lambda R \Leftrightarrow (yRx \Leftrightarrow y \in f x)$

for relation $R: Y \longleftarrow X$ and function $f: \mathcal{P}Y \longleftarrow X$ or, in a completely pointfree formulation

 $f = \Lambda R \iff R = \in \cdot f$

The Game characterization

Two players R and I discuss whether the transition structures are mutually corresponding

- *R* starts by chosing a transition
- I replies trying to match it
- if I succeeds, R plays again
- R wins if I fails to find a corresponding match
- *I* wins if it replies to all moves from *R* and the game is in a configuration where all states have been visited or *R* can't move further. In this case is said that *I* has a wining strategy
