# Calculating fault propagation in functional programs 

Daniel R. Murta \& José N. Oliveira HASLab - High Assurance Software Laboratory,<br>INESC TEC and University of Minho, 4700 Braga, Portugal pg23205@alunos.uminho.pt \& jno@di.uminho.pt<br>March 2013

#### Abstract

This file is a Haskell executable. It contains the experimental part of the homonym paper (submitted). Please unzip website.zip first and then move to the just created directory website. For the Haskell part run ```ghci -XNPlusKPatterns paper_haskell_matlab``` and follow the examples in part I below. For the MATLAB part, open MATLAB in the website/matlab directory, where all the executables can be found and run the scripts of part II.

Both parts follow the structure of the homonym paper.

## Part I Haskell

## 1 Introduction

## 2 Motivation

## 3 Mutual recursion

Fibonacci:

$$
\begin{aligned}
& f i b 0=0 \\
& \text { fib } 1=1 \\
& \text { fib }(n+2)=f i b n+f i b(n+1)
\end{aligned}
$$

Mutually-recursive equivalent:
$f i b^{\prime} 0=0$
$f i b^{\prime}(n+1)=f n$
f $0=1$
$f(n+1)=f i b^{\prime} n+f n$
For-loop combinator:

$$
\begin{aligned}
& \text { for } b i 0=i \\
& \text { for } b i(n+1)=b(\text { for } b i n)
\end{aligned}
$$

Linear Fibonacci:

$$
\begin{aligned}
& \text { fibl } n= \\
& \quad \text { let }(x, y)=\text { for loop }(0,1) n \\
& \quad \text { loop }(x, y)=(y, x+y)
\end{aligned}
$$

in $x$
Linear square:

$$
\begin{aligned}
& \operatorname{sql} n= \\
& \quad \operatorname{let}(s, o)=\text { for loop }(0,1) n \\
& \quad \operatorname{loop}(s, o)=(s+o, o+2) \\
& \quad \text { in } s
\end{aligned}
$$

## 4 Going probabilistic

Start with:

```
\(m f i b 0=\) return 0
mfib \(1=\) return 1
\(m f i b(n+2)=\)
    do \(\{x \leftarrow m f i b n ; y \leftarrow m f i b(n+1)\); return \((x+y)\}\)
```

Define:

$$
\operatorname{loop}(x, y)=\operatorname{do}\{z \leftarrow \text { fadd } 0.1 x y ; \text { return }(y, z)\}
$$

Re-define:

```
mfib \(0=\) return 0
mfib \(1=\) return 1
\(m f i b(n+2)=\) do \(\{x \leftarrow m f i b n ; y \leftarrow m f i b(n+1) ;\) fadd \(0.1 x y\}\)
```

Run mfib 4:

$$
\begin{array}{rr}
3 & 81.0 \% \\
2 & 18.0 \% \\
1 & 1.0 \%
\end{array}
$$

Define

$$
\begin{aligned}
& \text { mfibl } n= \\
& \quad \text { do }\{(x, y) \leftarrow \text { mfor loop }(0,1) n \text {; return } x\} \\
& \quad \text { where loop }(x, y)=\text { return }(y, x+y)
\end{aligned}
$$

where

$$
\begin{aligned}
& \text { mfor } b \text { i } 0=\text { return } i \\
& \text { mfor } b i(n+1)=\mathbf{d o}\{x \leftarrow \text { mfor } b i n ; b x\}
\end{aligned}
$$

Run $m f i b 5$ and $m f i b l 5$ and then $m f i b 6$ and $m f i b l^{\prime} 6$, to obtain the table in the paper - table 1 below.

Then define

```
\(m s q 0=\) return 0
\(m s q(n+1)=\mathbf{d o}\{m \leftarrow m s q n\); fadd \(0.1 m(2 * n+1)\}\)
```

and

```
\(m s q l n=\)
    do \(\{(s, o) \leftarrow\) mfor loop \((0,1) n\); return \(s\}\)
        where loop \((s, o)=\)
            do \(\{z \leftarrow\) fadd \(0.1 \mathrm{~s} o\); return \((z, o+2)\}\)
```

Run $m s q n$ and $m s q l n$ for $n=1 \ldots$ to check their probabilistic equality, as in the table (table 4 below).

## 5 Probabilistic for-loops in the LAoP

Define

$$
\text { ftwice }=\text { mfor }(\text { fadd } 0.12) 0
$$

Run ftwice 4:
*Main> ftwice 4
8 65.6\%
$6 \quad 29.2 \%$
4 4.9\%
$20.4 \%$
0 0.0\%
Define

$$
m f i b l^{\prime} n=
$$

$$
\text { do }\{(x, y) \leftarrow m \text { for loop }(0,1) n ; \text { return } x\}
$$

Run mfibl' 5:
*Main> mfibl' 5
$572.9 \%$
$316.2 \%$
4 8.1\%
2 2.7\%
$10.1 \%$

## 6 Probabilistic mutual recursion in the LAoP

Function $f$ :

```
f1= uniform [1..2]
f2=D[(1,0.3), (2,0.7)]
f3= return 2
f4=D[(1,0.75),(2,0.25)]
```

Function $g$ :

```
g 1 = D [(1,0.3), (2,0.7)]
g2=D[(1,0.4),(2,0.2),(3, 0.4)]
g 3 = D[(1, 0.1), (2,0.2), (3, 0.7)]
g4= return 2
```

## Function $k$ :

$$
k 1=D([((1,1), 0.24),((1,2), 0.08),((1,3), 0.08)]+[((2,1), 0.36),((2,2), 0.12),((2,3), 0.12)])
$$

Checking column 1:

$$
k 1=k 1 \equiv((m f s t \cdot k) \Delta(m s n d \cdot k)) 1
$$

| $(2,1)$ | $36.0 \%$ |
| ---: | ---: |
| $(1,1)$ | $24.0 \%$ |
| $(2,2)$ | $12.0 \%$ |
| $(2,3)$ | $12.0 \%$ |
| $(1,2)$ | $8.0 \%$ |
| $(1,3)$ | $8.0 \%$ |

## 7 Asymmetric Khatri-Rao product

## 8 Probabilistic mutual recursion resumed

```
msqlo \(n=\)
    do \(\{(s, o) \leftarrow\) mfor loop \((0,1) n\); return \(o\}\)
        where loop \((s, o)=\)
            do \(\{z \leftarrow\) fadd 0.1 s o; return \((z, o+2)\}\)
odd \({ }^{\prime} 0=\) return 1
odd \({ }^{\prime}(n+1)=\) do \(\{x \leftarrow\) odd \(n ;\) fadd \(0.12 x\}\)
\(m s q^{\prime} 0=\) return 0
\(m s q^{\prime}(n+1)=\) do \(\left\{m \leftarrow m s q^{\prime} n ; x \leftarrow\right.\) odd \(n ;\) fadd \(\left.0.1 m x\right\}\)
\(m s q l^{\prime} n=\)
        do \(\{(s, o) \leftarrow\) mfor loop \((0,1) n\); return \(s\}\) where
        loop \((s, o)=\) do \(\{\)
            \(z \leftarrow\) fadd 0.1 s \(o ; x \leftarrow\) fadd \(0.12 o ;\)
            return \((z, x)\}\)
```

## 9 Generalizing to other fault propagation patterns

Define

$$
\text { fcat }=\text { mfold }\left(\text { snd }_{0.1} \diamond \text { cons }\right)(\text { return }[])
$$

where

$$
\begin{aligned}
& \text { mfold }:: \text { Monad } m \Rightarrow((a, b) \rightarrow m b) \rightarrow m b \rightarrow[a] \rightarrow m b \\
& \text { mfold } f d[]=d \\
& \text { mfold } f d(h: t)=\text { do }\{x \leftarrow m f o l d f d t ; f(h, x)\}
\end{aligned}
$$

Run fcat "abc" to obtain:

| *Main> | fcat "abc" |
| :---: | :---: |
| "abc" | $72.9 \%$ |
| "ab" | $8.1 \%$ |
| "ac" | $8.1 \%$ |
| "bc" | $8.1 \%$ |
| "a" | $0.9 \%$ |
| "b" | $0.9 \%$ |
| "c" | $0.9 \%$ |
| "" | $0.1 \%$ |

Define

$$
\text { fcount }=\text { mfold }\left(\left(i d_{0.15} \diamond \text { succ }\right) \cdot \text { snd }\right)(\text { return } 0)
$$

Run fcount "abc":
*Main> fcount "abc"
3 61.4\%
$232.5 \%$
$15.7 \%$
$00.3 \%$
Define

$$
\text { pipe }=\text { fcount } \bullet \text { fcat }
$$

Run pipe "abc":
*Main> pipe "abc"
3 44.8\%
41.3\%
12.7\%
$01.3 \%$
Fusion - define

```
ffcount \(=m f o l d(m i x ~ 0.10 .15)(\) return 0\()\)
```

where $\operatorname{mix}$ p $q=\left(\right.$ choice $p$ return $\left(i d_{q} \diamond\right.$ succ $\left.)\right) \cdot$ snd
and run:
*Main> ffcount "abc"
$344.8 \%$
$241.3 \%$
1 12.7\%
$01.3 \%$

## Auxiliary

```
cons \((h, t)=h: t\)
nil \(=[]\)
add \((x, y)=x+y\)
zero \(=\underline{0}\)
one \(=\underline{1}\)
```

## Part II

## MATLAB

## 1 Introduction

## 2 Motivation

## 3 Mutual recursion

To run the recursive version of $f i b$, without injecting any faulty behaviour, run for instance:

```
>> execFibr(@nfAdd,5,10,4)
ans =
\begin{tabular}{lllll}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{tabular}
```

The first parameter of the command is, basically, the add function the command will use to calculate its result. In this case we are passing a non-faulty add (nfAdd), since we want a sharp Fibonacci. The next two parameters are the numbers of columns and rows, respectively, of the result matrix. In order to calculate (to see) $f i b$ 4, for example, one has to force, at least, 5 columns, because the first one corresponds to zero ( $f 00$ ). The last parameter corresponds to the actual input number we want to pass to the Fibonacci function. If matrix $(3,4)=1$ (matrix(line,column) with indexes beginning at 1) then $f i b(4-1)=(3-1)$ or fib3 $=2$. Thus, observing the matrix, we can see that fib $0=0$, fib $1=1 \ldots$ as it was supposed.

To run the linear version of $f i b$, without injecting any faulty behaviour, run for instance:

```
>> execFibl(@nfAdd,6,10,5)
ans =
```

| 1 | 0 | 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 1 | 0 | 0 | 0 |
| 0 | 0 | 0 | 1 | 0 | 0 |
| 0 | 0 | 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 1 |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 |

| $n$ | mfib $n$ |  | mfibl $n$ |  |
| ---: | ---: | ---: | ---: | ---: |
| 5 | 5 | $65.6 \%$ | 5 | $72.9 \%$ |
|  | 4 | $21.9 \%$ | 3 | $16.2 \%$ |
|  | 3 | $10.5 \%$ | 4 | $8.1 \%$ |
|  | 2 | $1.9 \%$ | 2 | $2.7 \%$ |
|  | 1 | $0.1 \%$ | 1 | $0.1 \%$ |
| 6 | 8 | $47.8 \%$ |  |  |
|  | 7 | $26.6 \%$ | $65.6 \%$ |  |
|  | 6 | $11.8 \%$ | 5 | $14.6 \%$ |
|  | 5 | $9.8 \%$ | 6 | $14.6 \%$ |
|  | 4 | $2.7 \%$ | 3 | $2.4 \%$ |
|  | 3 | $1.1 \%$ | 4 | $2.4 \%$ |
|  | 2 | $0.2 \%$ | 2 | $0.4 \%$ |
|  | 1 | $0.0 \%$ | 1 | $0.0 \%$ |

Table 1: Faulty Fibonacci (recursive and linear)

| 0 | 0 | 0 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | 0 |

Please note that, in this case, we increased the number of rows to 6 so that we could see the result of $f i b$ for 5 .

To run the linear version of $s q$, without injecting any faulty behaviour, run for instance:

```
>> execSql(@nfAdd,4,10,3)
ans =
```

| 1 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- |
| 0 | 1 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 1 |

Please note that, in this case, we used 10 for the number of columns of the result matrix, simply, because we know that $s q 3=9$, so we must have at least 10 rows to visualize 9 as result.

## 4 Going probabilistic

In this section we intend to inject some faults in the $s q$ and $f i b$ functions. To do this, instead of using a non-faulty add function as the first parameter of the commands in the previous section, we can use faulty ones.

To obtain the results displayed in table 1 presented in section 4 of the article run:

```
>> mfib(7,12)
```

```
ans =
    1.0000
\begin{tabular}{rr}
0 & 0 \\
0 & 1.0000 \\
0 & 0 \\
0 & 0 \\
0 & 0 \\

## 5 Probabilistic for-loops in the LAoP

## 6 Probabilistic mutual recursion in the LAoP

To obtain the results displayed in first diagram of section 6 in the paper run:

```
>> f = [0.5 0.3 0 0.75;0.5 0.7 1 0.25];
```

```
>> g = [0.3 0.4 0.1 0;0.7 0.2 0.2 1;0 0.4 0.7 0];
>> kr(f,g)
ans =
\begin{tabular}{rrrr}
0.1500 & 0.1200 & 0 & 0 \\
0.3500 & 0.0600 & 0 & 0.7500 \\
0 & 0.1200 & 0 & 0 \\
0.1500 & 0.2800 & 0.1000 & 0 \\
0.3500 & 0.1400 & 0.2000 & 0.2500 \\
0 & 0.2800 & 0.7000 & 0
\end{tabular}
>> fst(2,3)
ans =
    1
    0
>> snd(2,3)
ans =
\begin{tabular}{llllll}
1 & 0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 1 & 0 & 0 & 1
\end{tabular}
```

## 7 Asymmetric Khatri-Rao product

## 8 Probabilistic mutual recursion resumed

In this section we injected two faults to the square functions. They were called $s q$ ' and $s q l^{\prime}$ in the paper. To obtain the results displayed in table 3 present in section 8 of the paper, run the following commands:

```
>> msq2(4,12)
ans =
\begin{tabular}{rrrr}
1.0000 & 0 & 0 & 0 \\
0 & 1.0000 & 0.0100 & 0.0010 \\
0 & 0 & 0.0900 & 0.0001 \\
0 & 0 & 0.0900 & 0.0188 \\
0 & 0 & 0.8100 & 0.0024 \\
0 & 0 & 0 & 0.1029 \\
0 & 0 & 0 & 0.0219 \\
0 & 0 & 0 & 0.1968 \\
0 & 0 & 0 & 0.0656 \\
0 & 0 & 0 & 0.5905 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{tabular}
```

and

| $n$ | $m s q^{\prime} n$ |  | $m s q l^{\prime} n$ |  |
| :---: | ---: | ---: | ---: | ---: |
|  | 9 | $59.0 \%$ | 9 | $65.6 \%$ |
|  | 7 | $19.7 \%$ | 5 | $15.4 \%$ |
|  | 5 | $10.3 \%$ | 7 | $7.3 \%$ |
|  | 8 | $6.6 \%$ | 8 | $7.3 \%$ |
|  | 6 | $2.2 \%$ | 3 | $2.6 \%$ |
|  | 3 | $1.9 \%$ | 4 | $0.8 \%$ |
|  | 4 | $0.2 \%$ | 6 | $0.8 \%$ |
|  | 1 | $0.1 \%$ | 1 | $0.1 \%$ |
|  | 2 | $0.0 \%$ | 2 | $0.1 \%$ |

Table 3: Double faulty square functions

```
>> msql2(4,12)
ans =
\begin{tabular}{rrrr}
1.0000 & 0 & 0 & 0 \\
0 & 1.0000 & 0.0100 & 0.0010 \\
0 & 0 & 0.0900 & 0.0009 \\
0 & 0 & 0.0900 & 0.0261 \\
0 & 0 & 0.8100 & 0.0081 \\
0 & 0 & 0 & 0.1539 \\
0 & 0 & 0 & 0.0081 \\
0 & 0 & 0 & 0.0729 \\
0 & 0 & 0 & 0.0729 \\
0 & 0 & 0 & 0.6561 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{tabular}
```

## 9 Generalizing to other fault propagation patterns

This section was conceived so that we could extend faulty behaviour to functions with types other than the Naturals. In this case we opted for the Sequences type, and to do that we presented two particular functions over sequences which are the count and cat. The cat function is the identity of sequences and the count counts the number of elements of a sequence. These functions were also implemented with Matlab, however their output is bit more difficult to understand because, by the time we start dealing with sequences, the cardinality of the types grows very much.

To obtain the results of $f c a t " a b c$ " run the following command:
>> faultyCat $(3,3,3)$
Prompting the command, you realize that the output given is somewhat extensive - a matrix $40 \times 40$. The reason for this is very simple. faultyCat receives:

1. The number of different elements that can constitute the sequence. If you choose 3 , like in this case, you can imagine a sequence only with 1,2 and 3 as possible elements;
2. The maximum length of the sequences. If you choose 3 , like in this case, you can imagine sequences with $0,1,2$ or 3 as length;
3. The number of iterations the function is supposed to run.

When we pass to faultyCat those parameters we've just passed, it generates all the sequences possible respecting the parameters: 3 different elements and 3 as maximum length. There are 3 different lists with one element only, 9 with two elements and 27 with three elements and, lastly, the empty list. Doing the math, we have $1+3+9+27=40$ different sequences, and that's were the dimension of the result matrix comes from.

In order to easily understand the result matrix, scrolling up the screen is possible to visualize that a matrix called "columns" was calculated - this matrix indicates the order of the result matrix. So, to see, for instance what is the result given by faultyCat for a the sequence "abc", like in the paper, firstly you need to count the position of the sequence in the columns matrix, and then you need to look up, in the result matrix, the column with the number you got first. Thus, for the sequence "abc", looking it up in the columns matrix, we realize it stands in the $35^{t h}$ line, which is the sequence [1230]. Then, the $35^{t h}$ column in the result matrix is the following:
0.0010
0.0090
0.0090
0.0090
0
0
0
0.0810
0
0
0.0810
0.0810

## 0

0
0
This column is the result of faultyCat"abc", just like in the paper. To interpret this column, once again we have to rely on the columns matrix. The first row of faultyCat"abc" is 0.0010 and the first row the columns matrix is 0000 , which corresponds to the empty sequence ([]). This means that faultyCat" $a b c$ " $=[]$ with 0.1 per cent of probability. The same 'line of though" is applied to the remaining lines, which allow us to obtain the same result displayed in the paper:

| "abc" | $72.9 \%$ |
| :--- | ---: |
| "ab" | $8.1 \%$ |
| "ac" | $8.1 \%$ |
| "bc" | $8.1 \%$ |
| "a" | $0.9 \%$ |
| "b" | $0.9 \%$ |
| "c" | $0.9 \%$ |
| "" | $0.1 \%$ |

To execute fcount" abc" prompt the following command in matlab:

```
>> faultyCount(3,3,3)
```

This function has the same parameters faultyCat has, however, in this case, we are calculating the length of sequences, which means that the output type is Naturals, not Sequences as it was before. This means that the result matrix does not have to be as large as it was with faultyCat. The $35^{\text {th }}$ column of the result displays faultyCount"abc":
0.0034
0.0574
0.3251
0.6141

To execute fcount . fcat "abc":

```
>> count = faultyCount(3,3,3);
>> cat = faultyCat(3,3,3);
>> result = count*cat;
>> result(1:4,35)
ans =
    0.0130
    0.1267
    0.4126
    0.4477
```
